Biofilm is a thin, slimy film of bacteria that sticks to moist surfaces, such as those inside dental unit waterlines. Biofilm occurs in dental unit waterlines because of the long, small-diameter tubing and low flow rates used in dentistry, the frequent periods of stagnation, and the potential for retraction of oral fluids. As a result, high numbers of common water bacteria can be found in untreated dental unit water systems. A few disease-causing microorganisms found in untreated dental unit water include *Legionella, Pseudomonas aeruginosa,* and nontuberculous *Mycobacterium*.

Dental health care personnel and patients could be placed at risk of adverse health effects if water is not appropriately treated.
